Ionic liquids as Efficient Catalysts for The Glycolysis of Polyethylene Terephthalate

Department of Petroleum Applications, Department of Petrochemicals, Egyptian Petroleum Research Institute, Nasr City, Cairo 11727 and **Department of Chemistry, Faculty of Science, Benha University, Egypt.

THE GLYCOLYSIS of polyethylene terephthalate (PET) was studied using several ionic liquids as catalysts. The Lewis base ionic liquid, 1-butyl-3-methylimidazolium acetate [Bmim][OAc], exhibits higher catalytic activity for the glycolysis of PET, compared with 1-butyl-3 methylimidazolium chloride ([Bmim][Cl]) and 1-butyl-3-methylimidazolium bromide ([Bmim][Br]). The results revealed that the [Bmim][OAc] has a PET conversion of 75.1% and bis (2-hydroxyethyl) terephthalate (BHET) yield of 46.4% under the conditions of 1.0 g of [Bmim][OAc] with 20 g of ethylene glycol in the presence of 2.0 g of PET at 180°C after 2 hr of glycolysis. The main glycolysis product (BHET) was analyzed using XRD, NMR, EI-MS, FTIR, TGA and DSC.

Keywords: Catalysis, Ionic liquid, Glycolysis, Polyethylene terephthalate and Recycling.

Increased environmental awareness, legislative measures and public demand for environmental sustainability are leading to an increased interest in plastics recycling. The amount of plastic production has been increasing significantly each year, with uses including fiber, packing, containers and building materials, among others[1,2]. Poly (ethylene terephthalate) (PET) is a semi-crystalline thermoplastic polyester with high chemical and impact resistance at room temperature. PET is extensively used in diverse applications, such as textiles, high-strength fibers, photographic films and disposable soft-drink bottles, due to its excellent mechanical properties, chemical stability, safety, light weight, transparency and air-tightness[3,4], which has resulted in a continuously growing stream of PET material[5]. The total global PET consumption has risen to 54 million metric tons in 2010 and is expected to grow by 4.5% per year from 2010 to 2015[6]. Thus, the effective recycling of PET waste has been regarded as one of the most important ways of resolving “white pollution”, saving resources and protecting the environment[7,8]. Therefore, an ecologically safe method of recycling plastics, such as PET, remains an important scientific and societal goal.

At present, the conventional methods of PET recycling are mainly divided into physical methods and chemical methods. The physical methods of recycling
produce some plastic products with inferior properties. However, the chemical methods can recycle PET waste to produce monomers that can be used as raw materials to produce virgin plastic products. Considering the quality of the recycled products, chemical methods are particularly attractive and have been studied widely. These methods mainly include methanolysis, hydrolysis and glycolysis, which have been developed on commercial or pilot scales. Glycolysis is the most promising approach due to its advantages of low-volatility solvents and continuous production feasibility. The main product of the glycolysis of PET is the virgin monomer (BHET), which can be used to make PET production units, textile softeners and unsaturated polyester resins.

The glycolysis reaction is very slow in the absence of a catalyst and is an extremely sluggish process. In recent years, many catalysts have been developed for the glycolysis of PET, such as metal acetates (Zn, Co, Pb and Mn), titanium phosphate, solid superacids, metal oxides, carbonates and sulfates. However, these catalysts have several drawbacks, such as the need for high temperatures and high pressures, difficult separation of the catalyst from the depolymerized products, the occurrence of side reactions and the impurity of the products. Therefore, it is necessary to develop a new catalyst for the glycolysis of PET.

Recently, ionic liquids (ILs) have been used as environmentally friendly catalysts in the degradation of PET under mild conditions because of their adjustable physical and chemical properties, attracting the attention of scholars from various fields, such as synthesis, catalysis, separation and electrochemistry. The special properties of ionic liquids make it easier to separate the catalyst from the solid glycolysis products. Wang et al. used an ionic liquid as a catalyst for the glycolysis of PET; however, the conversion of PET and selectivity toward BHET were very low, and the process was very slow. They also studied the glycolysis of PET using a Fe-containing magnetic ionic liquid, which exhibited higher catalytic activity than conventional ILs. However, the monomer produced is very easily stained by the Fe-containing ILs.

The aim of this investigation was to apply the acetate-based ionic liquid [Bmim][OAc] as a catalyst in the glycolysis of PET to avoid the negative environment and health effects of chlorine-containing IL catalysts.

To the best of our knowledge, the use of [Bmim][OAc] as a catalyst for the glycolysis of PET has yet to be published.

**Experimental**

*Materials*

PET pellets (3.2 x 2.8 x 4 mm) were purchased from Hangzhou Zhenghan Biological Technology Co., Ltd. The intrinsic viscosity of PET was measured in a 60:40 (w/w) phenol/1,1,2,2-tetra-chloroethane solution at 25°C and found to be 0.64 dL g⁻¹. Using the Mark–Houwink method, the weight average molecular weight (4.1×10⁴ g mol⁻¹) was calculated from this intrinsic viscosity. Analytical-
grade ethylene glycol (EG), 1-butyl-3-methylimidazolium chloride ([Bmim][Cl]),
1-butyl-3-methylimidazolium bromide ([Bmim][Br]) and ethanol were obtained
from Sigma–Aldrich. 1,1,2,2-Tetrachloroethane, potassium acetate and phenol
were obtained from Merck.

Synthesis of 1-butyl-3-methylimidazolium acetate ([Bmim][OAc])

1-Butyl-3-methylimidazolium acetate ([Bmim][OAc]) was synthesized
according to the procedures described in the literature (28).

General procedure for the glycolysis of PET

A 50-ml round-bottom three-necked flask equipped with a thermometer and
a reflux condenser was loaded with 2.0 g of PET, 20.0 g of ethylene glycol and a
certain amount of catalyst. The glycolysis reactions were carried out under
atmospheric pressure at reaction temperatures ranging from 150°C to 190°C for
glycolysis times of 1–4 hr. The flask was immersed in an oil bath at a specific
temperature for the required time. When the glycolysis reaction was complete,
the undepolymerized PET pellets were quickly separated from the liquid phase
before the products precipitated. An excess amount of cold distilled water was
used to wash the undepolymerized PET pellets, and the water was then mixed
with the product fraction. The undepolymerized PET was collected, dried and
weighed. The conversion of PET is defined by Eq. (1):

\[
\text{Conversion of PET (\%) } = \frac{W_0 - W_1}{W_0} \times 100\% \quad \text{Eq. (1)}
\]

where \(W_0\) represents the initial weight of PET and \(W_1\) represents the weight of
undepolymerized PET. Meanwhile, the glycolysis product mixture was vigorously
agitated (cold distilled water would dissolve the remaining ethylene glycol, catalyst
and monomer) and then filtered. The collected filtrate was concentrated to
approximately 150 ml by a vacuum rotary evaporator at 50°C. The concentrated
filtrate was stored in a refrigerator at 0°C for 24 hr. White crystalline flakes were
formed in the filtrate and then separated and dried. This material was the
bis(hydroxyethyl) terephthalate (BHET) monomer. The fraction insoluble in cold
water was a mixture of the dimer and oligomers. The products were analyzed using
XRD, NMR, EI-MS, FTIR, TGA and DSC. The selectivity of the BHET monomer
is defined by Eq. (2), while the yield is defined by Eq. (3):

\[
\text{Selectivity of BHET (\%) } = \frac{W_{\text{BHET}}/MW_{\text{BHET}}}{W_{\text{PET,I}}/MW_{\text{PET}}} \times 100\% \quad \text{Eq. (2)}
\]

\[
\text{Yield of BHET (\%) } = \frac{W_{\text{BHET}}/MW_{\text{BHET}}}{W_{\text{PET,I}}/MW_{\text{PET}}} \times 100\% \quad \text{Eq. (3)}
\]
where \( W_{\text{PET, D}} \), \( W_{\text{PET, I}} \) and \( W_{\text{BHET}} \) refer to the weight of depolymerized PET, the initial weight of PET and the weight of BHET, respectively. \( MW_{\text{BHET}} \) and \( MW_{\text{PET}} \) are the molecular weights of BHET (254 g mol\(^{-1}\)) and the PET (192 g mol\(^{-1}\)) repeating unit, respectively.

**Characterization**

The main product was analyzed by \( ^1H \) NMR using an ECA 500 MHz instrument (JEOL, Japan) in DMSO-d6 solution. Fourier transform infrared spectroscopy (FTIR) measurements were performed using a Nicolet IS-10 FTIR instrument with KBr discs. The mass spectrum of the main product was obtained on an ISQ single-quadrupole MS (Thermo Scientific) instrument with electron ionization (EI). X-ray diffraction (XRD) patterns of the main product and PET material were recorded in the range 2\( \theta \) = 4–80º using a Philips powder diffractometer with Cu K\( \alpha \) radiation (\( k = 0.154 \) nm). The instrument was operated at 40 kV and 40 mA. The spectra were recorded at a scanning rate of 2º \( \theta \)/min. Thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) of the main product and PET were performed using a SDTQ 600 system (USA) by heating from room temperature to 1000ºC at a rate of 10ºC/min in a nitrogen atmosphere.

**Results and Discussion**

**Characterization of the synthesized ionic liquid**

Figure 1 shows the FTIR spectrum of the synthesized ILs. The spectrum of \([\text{Bmim}][\text{OAc}]\) (Fig. 1) shows that the major peaks in the IR spectra are assigned to acetate C=O bond stretching (1570-1579 cm\(^{-1}\)), C-O stretching (1379-1403 cm\(^{-1}\)), C–H stretching (2963-2966 cm\(^{-1}\)), C–C stretching (918 cm\(^{-1}\)), O–C–O bending (650 cm\(^{-1}\)), imidazole C–N stretching (1337 cm\(^{-1}\)), C–H stretching (3104 cm\(^{-1}\)), side chain C–H stretching (2874 cm\(^{-1}\)), and C–N–C bending (623 cm\(^{-1}\)). The C–H peaks between 3100 and 3200 cm\(^{-1}\) can be attributed to aromatic C–H stretching, whereas those below 3000 cm\(^{-1}\) can be attributed to aliphatic C–H stretching\(^{29,30}\). The observed aromatic C–H stretching is characteristic of C–H–O hydrogen bonds\(^{31}\).

Qualitative analysis of the main degradation product

To identify the structure of the main product in the degradation of PET in EG catalyzed by [Bmim][OAc], NMR, EI–MS, XRD, DSC, TGA and FTIR characterizations were performed. The main product was also identified by measuring the melting temperature, which is found to be 110.9°C. The EI–MS spectrum in Fig. 2 shows that the molecular weight of the main product is 254 g/mol, which is the same as that of BHET.

![EI-MS spectrum of BHET](image)

Figure 3 compares the XRD patterns of BHET and the PET material. PET exhibits a typical diffraction pattern due to the crystalline structure of this polyester, with broader diffraction peaks at 2θ = 16.4°, 17.7° and 23.0°. The diffraction peaks of BHET are narrower and more intense than those of PET, which illustrates that the BHET obtained by this method has a high crystallinity and a different crystalline structure than PET.

The DSC curve in Fig. 4 shows a sharp endothermic peak at 110ºC. The melting onset temperature and peak temperature of BHET are 110.9 and 110ºC, respectively.

The TGA curves of the PET material and BHET are illustrated in Fig. 5. The TGA curve of PET shows significant weight loss at 400ºC, which is attributed to the thermal decomposition of PET \(^{32, 25}\). The TGA curve of BHET exhibits two clear weight losses. The first is approximately 32% at an onset temperature of 240ºC due to the thermal decomposition of BHET. During the heating process in TGA analysis, BHET repolymerizes to PET. The other loss is approximately 60% at an onset temperature 400ºC due to the thermal decomposition of PET produced by the BHET thermal polymerization during TGA analysis \(^{32}\).

Ionic Liquids as Efficient Catalysts …

Fig. 5. TGA curves of BHET and PET.

Figure 6 shows the FTIR spectra of the BHET product and PET material. The FTIR spectra of the BHET monomer clearly showed an OH band at 3450 cm\(^{-1}\) and 1135 cm\(^{-1}\), C=O stretching at 1715 cm\(^{-1}\), alkyl C-H at 2879 and 2954 cm\(^{-1}\) and aromatic C-H at 1411-1504 cm\(^{-1}\), which are all present in BHET\(^{33,34}\).

Fig. 6. FTIR spectra of BHET and PET.

The H\(^1\) NMR spectrum of BHET is presented in Fig. 7. The single signal at \(\delta\) 8.1 ppm indicates the presence of the four aromatic protons of the benzene ring. The triplet at 4.3 ppm and the quartet at 3.7 ppm represent the methylene protons of COO-CH\(_2\) and CH\(_2\)-OH, respectively. The triplet at \(\delta\) 4.9 ppm is characteristic of the protons of the hydroxyl. The H\(^1\) NMR spectrum also agrees very well with those reported in the literature\(^{35-37}\).

Effect of catalysts on the glycolysis of PET

The catalytic performance of various ionic liquid catalysts was examined in the glycolysis reaction of PET. As seen from Table 1, in the presence of the Lewis neutral ionic liquids [Bmim][Br] and [Bmim][Cl], no glycolysis of PET took place. However, when [Bmim][OAc] was used as a Lewis base catalyst under the same conditions, the conversion of PET was 75.1%, the selectivity of BHET was 61.9%, and the yield was 46.4%. This demonstrates that [Bmim][OAc] has an excellent catalytic activity for the glycolysis of PET, as the degradation reaction occurred under relatively mild conditions with a higher reaction extent.

Degradation mechanism for PET glycolysis

There has been some debate on the mechanism of the degradation of PET. Researchers (27,39,40) have reported that the degradation of PET resulted from the cleavage of the ester group in PET. In some studies, it has been found that the degradation of PET occurred in the amorphous phase and at the chain folds on the crystal surface (41,42).

The mechanism and supposed pathway of the glycolysis of PET catalyzed by the Lewis base ionic liquid [Bmim][OAc] (43,44) are illustrated in Scheme 1; this process is a Lewis base catalytic reaction. When [Bmim][OAc] is added, it is assumed that there exists a synergic effect between the cation and anion of this catalyst (45). The cation of this ionic liquid, [Bmim]⁺, interacts with the carbonyl oxygen (C=O) in the ester of PET. The oxygen in the hydroxyl group of ethylene glycol then attacks the carbon cation of the ester group, forming a tetrahedral intermediate. Meanwhile, the anion of the catalyst [OAc]⁻ interacts with the hydrogen in the hydroxyl group of ethylene glycol, resulting in the oxygen of ethylene glycol becoming more negative and better able to attack the carbon cation of the ester group, breaking the C–O bond in PET. Lastly, the hydrogen in ethylene glycol leaves and combines with [OAc]⁻ to form acetic acid as an intermediate. The acetic acid then partially dissociates to give H⁺ and an acetate ion. In this case, the EG molecule and carbon are connected, a new ester group is formed, and the chain of PET is cleaved. The electrons on the oxygen in –O(Bmim⁺) then transfer, forming C=O. The acyl-oxygen cleaves and the –OCH₂CH₂– group leaves, combining with H⁺ to form HOCH₂CH₂⁻.

The depolymerization of PET proceeded step-by-step, and oligomers, dimers and monomers were generated sequentially. With the progress of the reaction, an increasing number of BHET monomers emerged, which might polymerize into dimers or oligomers, creating a chemical equilibrium (27).

Conclusion

In summary, it is demonstrated that [Bmim][OAc] could behave as an efficient and eco-friendly catalyst for the glycolysis of PET in ethylene glycol. Using [Bmim][OAc] (1.0 g) with 20 g of EG and 2.0 g of PET, it is found that only 2 h of glycolysis at 180°C is sufficient for the conversion of PET to reach 75.1% and the yield of BHET to reach 46.4%. The synergistic effect of the cation and anion in the Lewis base ionic liquid [Bmim][OAc] facilitates the attack of the oxygen in ethylene on the carbon cation of the ester group. The acetate-based ionic liquid [Bmim][OAc] might have the potential to substitute traditional compounds to catalyze the glycolysis of PET in industrial production.
