Efficient and clean synthesis of Schiff base as a new ligand, 6-ethoxy-2-(2-methoxy-benzylideneamino)benzothiazole have been synthesized in equimolar reaction of 2-amino-6-ethoxy-benzothiazole with 2-methoxy benzaldehyde using microwave technique. The prepared Schiff base was reacted with some transition metal ions Ni(II) , Cu(II), Pd(II), Ag(I) and Au(III) in equimolar ratio (M:L, 1:1) using microwave technique. The stereochemistry and the bonding characteristics of the ligand and its complexes were achieved based on elemental analysis, FT-IR, UV-Vis., ¹HNMR and ESR as well as Thermo-Gravimetric Analysis (TGA). The thermal dehydration and decomposition of Ni(II), Cu(II) and Ag(I) complexes were studied kinetically using the integral method applying the Coats–Redfern and Horowitz–Metzger equations. The reactivity of ligand and its Au(III) complex were studied against breast carcinoma cell. The antimicrobial activity of ligand and its Ag(I) complex studied against the bacterial (positive and negative) grams and fungal strains.

Keywords: Microwave synthesis, Breast cancer and Thermal analysis

Introduction

Microwave-assisted synthesis is a branch of green chemistry. Microwave irradiated reactions under solvent free or less solvent conditions are attractive offering reduced pollution, low cost and offer high yields together with simplicity in processing and handling. The salient features of microwave approach are shorter reaction times, simple reaction conditions and enhancements in yields [1, 2]. Microwave heating has been widely used in organic and inorganic synthesis and Metal–Organic Frame works (MOFs) is well known [3]. However, it has not been less popular with the activation of coordination compounds [4]. Reports on the synthesis of metal complexes by microwave methods have been comparatively less [5, 6]. These Schiff bases are of great interest because of their structural variety, varied denticities and subtle steric and/or electronic effects leading to complexes of different dimensionalities. Moreover, their ability to form non-covalent interactions such as hydrogen bonding interactions. In the 1950s, a number of 2-aminobenzothiazoles were intensively studied as central muscle relaxants. Since then, biologist’s attention was drawn to this series when pharmacological profile of Riluzole (6-trifluoromethoxy-2-benzothiazolamines, marketed as Rilutek), as a Glutamate neurotransmission inhibitor was discovered. After that benzothiazole derivatives have been extensively studied and found to have diverse chemical reactivity and broad spectrum of activity [7, 8]. Benzothiazole derivatives are known to have wide spectrum of therapeutic activities such as: Antitumor activity [9-11], Antibacterial...
and antifungal activity [12, 13], Antihelmintic activity [14, 15], Antiviral activity [16], Antimalarial activity [17], Antileishmanial, Antischistosomal activity [18], Anti-Inflammatory activity [19, 20], Anticonvulsant activity [21, 22] and Anti-Diabetic activity [23, 24]. Various investigations have proved that binding of a drug to metallo elements enhances its activity and, in some cases, the complex possesses even more healing properties than the parent drug [25]. In the present study metal ions of nickel (II), copper(II), palladium(II), silver(I) and gold(III) have been focused due to their smaller size and comparatively higher nuclear charge and thus have a great affinity to form coordination compounds with 6-ethoxy-2-(2-methoxy benzylideneamino) benzothiazole as a novel Schiff base of benzothiazole-derivatives.

Experimental

Material and methods

All chemicals used were of annular grade. Microwave assisted reactions were carried out in a domestic microwave energy output 900 W, frequency 2450 MHz, manufactured by DAEWOO technologies corporation, model: KOR-9G2B, Korea and the microwave reactions were performed using on/off cycling to control the temperature, the reactions were monitored by thin layer chromatography (TLC) with Merck percolated silica plates. Melting points were recorded in open capillaries on Thiel’s tube melting point apparatus and are uncorrected. The UV-vis range (200–900 nm) using Perkin Elmer Lambda 35 UV/Vis spectrometer at Al-Azhar University. The Fourier transform infrared spectra with the samples dissolved in KBr were recorded on Vertex 70 Analyzer, Bruker, USA from 400–4000 cm⁻¹ and magnetic susceptibility of prepared complexes were carried out at Mansoura University, Cairo, Egypt. The ESR spectra of the prepared complexes were carried out at Mansoura University, Cairo, Egypt. The H NMR spectra were recorded at Cairo University, Cairo, Egypt. Using Agilent NMR400 MHz spectrometer at 300 MHz in dimethylsulphoxide (DMSO-d₆), tetramethylsilane (TMS) was used as an internal reference and chemical shifts are quoted in δ (ppm). Mass spectra were performed by a Shimadzu-GCMS-QP1000 EX using the direct inlet system, Antitumor Evaluation, read the absorbance at 490 nm using ELISA reader (Sun Rise, TECAN, INC, USA) and antimicrobial activity were studied at Fermentation Biotechnology & Application Microbiology (Ferm-BAM) Center, Al-Azhar University, Cairo, Egypt.

General procedure for synthesis of 6-ethoxy-2-(2-methoxybenzylideneamino)benzothiazole Schiff base Ligand.

The equimolar (1:1) ratio of 2-amino-6-ethoxybenzothiazole (1.942 g, 0.01 mol) with 2-methoxy benzaldehyde (1.361 g, 0.01 mol) was mixed thoroughly in a grinder. The reaction mixture was then irradiated by the microwave oven by taking drops of ethanol. The reaction was completed in 1.5-2.0 mins with high percentage yield (95 %), yellow product, with m.p. of 128 °C. The resulting product was then recrystallized with ethanol and finally dried under reduced pressure over anhydrous CaCl₂ in desiccators. The progress of the reaction and purity of the product was monitored by TLC using silica gel G.

6-ethoxy-2-(2-methoxybenzylideneamino) benzothiazole Schiff base Ligand

The prepared Schiff base is then characterized IR (KBr, cm⁻¹): 1590 (HC=N), 1223 (C-O methoxy), 1554 (C=N, thiazole ring), 2990(C-H, aromatic), 2920(C-H, aliphatic). ¹H NMR (DMSO-d₆, δ, ppm) (Fig. 1): 1.35 (t, 3H, CH₃), 3.86 (s, 3H, O-CH₃), 4.09 (q, 2H, CH₂ adjacent to CH₃), 7.04-8.03 (aromatic H, aromatic), 8.16 (s, 1H, CH=N) [26], Elemental analysis: C% (found=58.01, calc.=57.69), H% (found=5.18, calc.=5.16), N% (found=8.92, calc.=8.97). Anal. Calcd. for (C₁₇H₁₆O₃N₃S) · MWT = 312.39, [M⁺]=312.

General procedure for the synthesis of complexes

The ligand and the metal salts; Ni(CH₃COO)₂.4H₂O, Cu(CH₃COO)₂.H₂O, PdCl₂, AgNO₃ and HAuCl₄ were mixed in (1:1) of (metal: ligand) ratio thoroughly in a grinder. The reaction mixtures were then irradiated by the microwave oven by taking drops of ethanol. The reaction was completed in 2-5 mins with high yields. The resulting product was then recrystallized with ethanol and ether and finally dried under reduced pressure over anhydrous CaCl₂ in a desiccator.

The progress of the reaction and purity of the product was monitored by TLC using silica gel G. The same method was used for the preparation of all complexes (Scheme 1). Physical, analytical and spectral data are given in Tables 1 and 2.

**Biological assays**

**Antimicrobial evaluation**

The synthesized ligand and its Ag(I) complex were screened for their antimicrobial activity against six different test organisms having environmental and clinically importance the antimicrobial activity of synthesized compounds was determined using agar well diffusion method. The ligand and Ag(I) were tested in vitro for their antibacterial activity against staphylococcus aureus and Streptococcus mutans (Gram positive bacteria), Escherichia coli, Pseudomonas aeruginosa and klebsiella (Gram negative bacteria) and Candida albicans (Fungi) using nutrient agar medium. Ampicillin, Gentamicin and Nystatin were used as standard drugs for Gram positive, Gram negative and Fungi, respectively. DMSO was used as solvent control. The compounds were tested at a concentration of 15 mg/ml against both bacterial and fungal strains.

*Disc diffusion method:* The sterilized media was poured onto the sterilized Petri dishes (20-25 ml, each petri dish) and allowed to solidify at room temperature. Microbial suspension was prepared in sterilized saline equivalent to McFarland 0.5 standard solution (1.5x 105 CFU ml⁻¹) and its turbidity was adjusted to OD= 0.13 using spectrophotometer at 625 nm. Optimally, within 15 minutes after adjusting the turbidity of the inoculum suspension, a sterile cotton swab was dipped into the adjusted suspension and was flooded on the dried agar surface then allowed to dry for 15 minutes with lid in place. Wells of 6 mm diameter was made in the solidified media with the help of sterile borer. 100 μl of the solution of the tested compound was added to each well with the help of micropipette. The plates were incubated at 37°C for 24 hrs. and viable cells yield was determined by colorimetric method, growth inhibition of cells was calculated spectrophotometrically using a standard method with crystal violet solution (1%) [12]. The optical density (OD) of each well was measured at 490 nm with an ELIZA, plate reader. Cisplatin (Sigma) was employed as the standard antitumor drug. The percentage of cell survival was calculated as follows:

\[
\text{Survival fraction} = \frac{\text{OD (treated cells)}}{\text{OD (control cells)}}
\]

The little percentage of DMSO present in the wells (maximal 0.1 %) was found not to affect the experiment. After incubation of the cells for 24 hrs. at 37°C, Various concentrations of sample (50, 25, 12.5, 6.25, 3.125 and 1.56 μg) were added, and the incubation was continued for 48 hrs. and viable cells yield was determined by colorimetric method, growth inhibition of cells was calculated spectrophotometrically using a standard method with crystal violet solution (1%) [12]. The optical density (OD) of each well was measured at 490 nm with an ELIZA, plate reader. Cisplatin (Sigma) was employed as the standard antitumor drug. The percentage of cell survival was calculated as follows:

\[
\text{Survival fraction} = \frac{\text{OD (treated cells)}}{\text{OD (control cells)}}
\]

The IC50 value is the concentration required to produce 50% inhibition of cell growth. The results are compared with a similar run of Cisplatin as an antitumor compound.

**Results and Discussion**

The Schiff base ligand was prepared by the condensation reaction of 2-methoxy benzaldehyde with 2-amino-6-ethoxy-benzothiazole under microwave irradiation as shown in Scheme 1. The synthesized Schiff base ligand was soluble in ethanol on heating only, while in dioxane, DMF and DMSO at room temperature. The structure of the ligand was established and reported elsewhere with the help of their IR, 1H NMR and microanalytical data. The compound was used in vitro screening experiments. The cancer cells were obtained frozen from Vacsera Tissue Culture Unit, Cairo, Egypt and the experiments were carried out in Center of the fungus and its applications, Al-Azhar University.

Fig. 1. 1HNMR Spectra of the Ligand.

Scheme 1. Preparation of the ligand and its metal complexes 1-5
for the complexation reaction with metal ion complexes. All of the newly synthesized metal complexes (1–5) were air and moisture stable (Table 1) at room temperature. They were prepared by the stoichiometric reaction of the corresponding metal salts and the respective ligand in the molar ratio M:L of 1:1. Physical measurements and analytical data of the complexes 1–5 are given in Tables 1 and 2.

**IR spectra**

The characteristic bands of IR spectra of ligand and their metal complexes are reported in experimental section and in Table 2. The ligand possessed potential donor sites like azomethine linkage (-C=N) and methoxy group (-OCH₃) which have tendency to coordinate with the metal ions. The IR spectra of the ligand showed the peaks at 1591 and 1223 cm⁻¹ due to vibration of (C≡N) and (C-O-C) respectively while the peaks at 2920 and 2990 cm⁻¹ due to vibration of aliphatic and aromatic (C-H) [26]. The comparison of the IR spectra of Schiff base ligand with corresponding metal complexes gave a different mode of absorption in complexation of ligand with the metal ions. The C≡N stretch shows both a positive and negative shift on complexation. We have observed a positive shift of azomethine to higher frequency at (1593-1596) cm⁻¹ for Nickel, Palladium and Silver complexes while a negative shift of azomethine to lower frequency at (1567, 1590) cm⁻¹ for the other complexes representing the involvement of the azomethine-N in the complex formation, while, the methoxy groups (O-CH₃) band originally appearing at 1223 cm⁻¹ in the spectra of the ligands shifted to lower frequency at (1211–1221) cm⁻¹ in spectra of metal complexes.

In all the metal complexes, a new band appeared at 511–515 cm⁻¹ due to ν(M–N) vibrations indicating the coordination of nitrogen of azomethine. While the bands at 420–472 cm⁻¹ due to ν(M–O) indicating the coordination of oxygen of methoxy group with the metal ions [28].

For Ni(II) and Cu(II) complexes Other bands ascribed negative OAc were detected at (1330 and 1427) cm⁻¹ and (1342 and 1415) cm⁻¹, respectively, suggesting vₛ and vₚₚ carboxylic modes. The large difference between the vₛ and vₚₚ frequencies confirmed the coordination of acetate as a unidentate anion through the C-O moiety of the carboxylic group [28].

**Mass spectra of the ligand**

The mass spectral data and fragmentation pattern of the Schiff base ligand clearly justify, the formation of the ligand possessing proposed structures and their bonding pattern. The spectra of molecular ion peak m/z 312 (Calcd. 312.39) of \([\text{C}_{17}\text{H}_{16}\text{N}_{2}\text{O}_{2}\text{S}]^+\) which loses a methyl group to give a fragment at m/z 297 of \([\text{C}_{16}\text{H}_{13}\text{N}_{2}\text{O}_{2}\text{S}]^+\). The fragmentation pattern followed the cleavage of \(\text{C}_{17}\text{H}_{16}\text{NO}\) to give a fragment at m/z 165 of \([\text{C}_{8}\text{H}_{7}\text{NOS}]^+\). Which cleaved to remove N-S giving a fragment at m/z 121 of \([\text{C}_{8}\text{H}_{9}\text{O}]^+\) which in turn loses \(\text{C}_{2}\text{H}_{5}\text{OH}\) to give to give a benzene fragment at m/z 74 of \([\text{C}_6\text{H}_{3}]^+\). Another pathway may be considered, in which the ligand cleaved to remove ethyl group to give a fragment at m/z 283 of \([\text{C}_{15}\text{H}_{11}\text{N}_{2}\text{O}_{2}\text{S}]^+\). The fragmentation pattern followed the cleavage of C-O to give a fragment at m/z 255 of \([\text{C}_{14}\text{H}_{11}\text{N}_{2}\text{OS}]^+\) as shown in fragmentation pattern of the ligand in Scheme 2 and Fig. 2.

![Fig. 2. Mass Spectra of the Ligand.](image-url)
Electronic spectra and magnetic properties

The electronic spectral and magnetic moment (B.M) values of the ligand and its metal complexes at room temperature were of Ni(II), Cu(II), Ag(I), Pd(II) and Au(III) complexes are recorded in Table 2. The electronic spectra of ligand at 26738 cm\(^{-1}\), 32468 cm\(^{-1}\) and 33222 cm\(^{-1}\) refers to \(n\pi^*\), \(\pi\pi^*\) of C=N and phenyl ring transitions, respectively. The electronic spectra of Ni(II) complex, the absorption band at 26624 cm\(^{-1}\) are assigned to the transition \(^3T_1(F) \rightarrow ^3T_1(P)\) suggesting a tetrahedral geometry around Ni(II) ion with magnetic moment values 3.02 B.M for Ni(II) [29]. For Cu(II) complex exhibited low-energy absorption band at 18450 cm\(^{-1}\) assigned to \(2B_{2g} \rightarrow 2E\) transition. The high-energy band at 23585 cm\(^{-1}\) is due to ligand to metal charge transfer (LMCT). On the basis of which a tetrahedral geometry is suggested for Cu(II) complex [30], the obtained magnetic moment value 1.95 B.M for Cu(II) complex are indicative of one unpaired electron per Cu(II) ion for \(d^9\)-system suggesting tetrahedral structure. For Ag(I) absorption band at 24390 cm\(^{-1}\) are assigned MLCT in a triagonal geometry confirmed by the diamagnetic properties [31]. In Pd(II) complex the two absorption bands at 26315 cm\(^{-1}\) and 27100 cm\(^{-1}\) are assigned respectively to the transitions \(^1A_{1g} \rightarrow ^1B_{1g}\) and \(^1A_{1g} \rightarrow ^1E_{1g}\) and the diamagnetic properties suggested a square-planar geometry around Pd(II) ion [32]. In Au(III) complex. The absorption band at 22448 cm\(^{-1}\) are assigned respectively to the transitions \(^6A_{1g} \rightarrow ^6E_{1g}\) and the diamagnetic properties suggested an octahedral geometry around Au(III) ion.

ESR Spectrum

The ESR spectra of Cu(II) complex were recorded on X-Band at frequency (9.7) GHz under the magnetic field strength (3480) G, recorded at room temperature. The spectra of the complex exhibited a single anisotropic broad signal with hyper structure indicated the contribution of free acetate ligand with complex formation. The anisotropic spectrum of ESR Cu(II) showed a \(g_{||} \geq g_{\perp}\) with the following values \(g_{\perp} = 2.08\) and \(g_{||} = \ldots\)

Scheme 2. Proposed mass fragmentation pattern of the ligand.
The thermogram of [Ag(L)NO$_3$] shows three decomposition steps; The first step at a temperature range of (67-180) °C corresponds to the loss of NO$_3$ (13.2 %). The second and third steps of decomposition at ranges of (207-248 and 470-542) °C, respectively, correspond to the loss of ethoxy-benzothiazole with MF of (C$_{13}$H$_{16}$NOS) (37.15 %) and the last organic part (C$_{14}$H$_{17}$N) (25.1 %) leaving Ag$_2$O (24.5 %) as a residue. Thermal decomposition scheme of metal complexes (1,2 and 4) are shown in scheme 3.

Biological activity.

Antimicrobial activity

To contribute to the field of bioinorganic chemistry, the synthesized ligand and its Ag(I) complex were tested against bacterial and fungal strains by disc diffusion method. The microorganisms used in the present investigations included bacterial and fungal strains. Bacterial strains; Gram positive bacteria (Staphylococcus aureus (ATCC:6538) and Strepococcus mutans (ATCC:25175)), Gram negative bacteria (Klebsiella pneumonia (ATCC:4415), Pseudomonas aeruginosa (ATCC:27853) and Escherichia coli (ATCC:3008)) and fungal strains; Candida albicans (ATCC:10231). The results were compared with those of the standard drugs (Gentamicin for Gram positive bacteria, Ampicillin for gram negative bacteria and Nystatin for fungal strains) and calculated the diameter of inhibition zone for each by mm.

Antimicrobial activity of Ligand and its Ag(I) complex

The antimicrobial activity of ligand and its Ag(I) complex against the bacterial and fungal strains were tested and evaluated. Table 5 shows the antimicrobial activity of ligand against the tested bacterial and fungal strains. Our results
MICROWAVE IRRADIATION SYNTHESIS AND ANTI-BREAST CARCINOMA...

Scheme 3. Thermal decomposition of metal complexes (1, 2 and 4)

Fig. 3. Thermal analysis (TG) of Ni (1), Cu (2) and Ag (4) complexes.

showed no inhibition effect on the growth of the bacterial and fungal strains by the ligand excepted the effect on the growth of Klebsiella pneumonia (ATCC:4415) and Staphylococcus aureus (ATCC:6538) with inhibition zones 13.3 mm and 10.7 mm, respectively. While the Ag(I) complex exhibited good antimicrobial activity against both bacteria (Gram-negative & Gram-positive bacteria) and fungal strains. It showed higher antibacterial activity against Pseudomonas aeruginosa (ATCC:27853) and Candida albicans (ATCC:10231) with inhibition zone 27.3 and 13.7 mm respectively, while appearance moderated to weak activity against Klebsiella pneumonia (ATCC:4415), Escherichia coli (ATCC:3008), Staphylococcus aureus (ATCC:6538), and Streptococcus mutans (ATCC:25175) with inhibition zone 18.7, 15.3, 13.7 and 11.7 mm, respectively. Hence the antimicrobial activity after complexation with Ag(I) is enhanced as compared to that of the free ligand.

Anticancer activity

The Schiff base ligand, L and its Au(III) complex were evaluated for human anti-cancer activity against MCF-7 cells. The reported results in terms of IC_{50} value for ligand is 15.1 μg/ml while for its gold complex IC_{50} value is 5.56 μg/ml (Fig. 4). For comparison purposes, the cytotoxicity of cisplatin, as standard antitumor drug, was evaluated and produced IC_{50} value (7.22 μg/ml) under the same conditions, where IC_{50} is the concentration which can reduce the growth of cancer cells by 50%. The results classify these compounds as chemotherapeutically significant. The rank order of potency as a function of chelated metal ion follows the order L< S< Au(III) against MCF-7 cancer cells. The data indicate that the in vitro IC_{50} value for Au(III) against the cell lines is lower than the Ligand and, even, the standard, the activity of ligand could be explained by the solubility effect as fairly good relationship could

Zone of inhibition is expressed in the form of mean ± standard deviation (mm). NA: No activity Well diameter (6mm) -100 µ was tested.

*Egypt. J. Chem. 62, No. 3 (2019)*
be seen between activity and solubility of the compounds. The binding of a ligand to Au(III) ion enhances its activity[25] and gives IC$_{50}$ value lower than the standared under the same conditions.

Conclusions

The newly synthesized Schiff bases ligand obtained from condensation of 2-amino-6-ethoxy-benzothiazole with 2-methoxy benzaldehyde using microwave technique act as bidentate ligand, which coordinated through the azomethine-N and methoxy-O to the metal ions; Ni(II), Cu(II), Pd(II), Ag(I) and Au(III). The thermal dehydration and decomposition of Cu(II), Ni(II) and Ag(I) complexes show elimination of water, acetate then organic content and MO remained as a residue. The activation energy of Ag(I)complex is higher than Ni(II) and Cu(II) as expected with decreasing in the radius. The cytotoxicity activities tested against (MCF-7) human tumor cell lines. The binding of a ligand to Au(III) ion enhances its activity to give IC$_{50}$ value lower than the standared. The antimicrobial activity of ligand and its Ag(I) complex against the bacterial and fungal strains showed that the activity of the ligand after complexation with Ag(I) is enhanced as compared to that of the free ligand.
