Preparation of Sulfated Zirconia Catalyst Loaded by Copper in 'Nano-scale: Green Application' to Synthesis of Biolubricant

Amina H. Ibrahim[*]**, Hussin Al-Shafey Ismail, Doaa S. El-Desouki, Samira M. Abdel-Azim, Noha A. K. Aboul-Gheit**
Egyptian Petroleum Research Institute, Cairo, Egypt.

THIS STUDY investigates the activity of copper-doped catalysts supported on sulfated zirconia (SZ) for the esterification of Free Fatty Acid (FFA). Three catalysts SZ, Cu/SZ (sol) and Cu/SZ (imp) were prepared. The latter two catalysts contain 10% Cu supported on sulfated zirconia (Cu/SZ) prepared by wet impregnation (Cu/SZ/ (imp)) and sol-gel method (Cu/SZ/ (sol)). The catalysts were characterized by X-ray diffraction (XRD), NH$_3$ Temperature Programmed Desorption (TPD), N$_2$ adsorption, Fourier transform infrared spectroscopy, and imaged by scanning electron microscopy. The XRD analysis showed that, the loading of Cu in the zirconia structure has stabilized the tetragonal zirconia phase, which is the most active phase. Also, the formation of Cu$_2$O and (CuO-ZrO) composite has been proved for the sol-gel preparation technique. The TPD illustrated that the incorporation of Cu ions in the lattice of zirconia via sol-gel technique has lowered the acidity of the catalyst much more than impregnation technique. As a green application, different concentrations of the prepared catalysts were used for preparation of biolubricants by direct esterification of FFAs. The Cu/ SZ/ (sol) catalyst has the highest activity. The percentage yields of synthesized biolubricants reached 99.8% when 0.3 % from the selected catalyst was utilized. Pour point, Flash point, Viscosity index, Apparent Viscosity and Percentage yield values of synthetic ester oils were evaluated.

Keywords: Sulfated zirconium, Biolubricant, Green application, Sol-gel, Free fatty acid.

Abbreviations   :

Proton nuclear magnetic resonance ^{1}HNMR; apparent viscosity AV; 'Deuterated chloroform' solution CDC$_{13}$; 10% Cu supported on sulfated zirconia Cu/SZ; 1-Decanol DA; flash point FP; Fourier transform infrared spectroscopy FTIR; Gel permeation chromatography GPC; metal impregnation method (imp); oleic acid OA; pour point PPT; P-Toluene sulphonic acid monohydrate PTSA; size exclusion chromatography SEC; scanning electron microscopy SEM; sol-gel method (sol); sulfated zirconia SZ; temperature programmed desorption TPD; viscosity index VI; X-ray diffraction XRD.

Introduction

Biolubricants have significant advantages compared with common lubrication products; they are non-toxic and biodegradable [1,2]. Using them, it is not necessary to add anti-oxidants, viscosity index improvers, stabilizers, or detergents [3-5].

In addition, they can lubricate over a wider temperature range because their viscosity does not vary with temperature [6].

The main raw materials for biodegradable lubricants are of vegetable origin. Synthetic biolubricant can be prepared by esterification of free fatty acids (FFAs) derived from vegetable oils; with alcohols in the presence of catalysts. The esterification reactions are commonly catalyzed by acidic based homogenous or heterogeneous catalysts, using principally sulphuric or phosphoric acids. The heterogeneous

catalysts are more favorable to overcome many problems facing the homogenous catalysts, like vessel corrosion and catalyst separation [7].

Several solid acid catalysts have been reported to produce esters from vegetable oils [8-13]. In the present work, biolubricants were synthesized from esterification reaction of FFAs and methanol using sulfated zirconia as a heterogeneous catalyst. The surface acidity of SZ is strongly dependent on the crystallographic phase of zirconia. In the sulfated state, tetragonal zirconia exhibits higher surface acidity and catalytic activity than the more stable, monoclinic zirconia. Surface acidity is the determining factor for the initial activity of heterogeneous FFA esterification catalysts [14, 15].

The SZ system offers the notable advantage of high selectivity for FFA esterification even in the presence of excess alcohol. The use of excess alcohol in FFA esterification promotes side reactions such as alcohol dehydration (to form dimeric ether). It is known that SZ exhibits a relatively low activity for alcohol dehydration and high selectivity for esterification in the presence of excess alcohol, and is thus suitable as a catalyst for reactive-distillation-assisted FFA esterification, in high alcohol/ acid ratios [16].

A common approach for improving the activity and durability of SZ is forming mixed oxides with other metal oxide components. Jiang, et al. [17] reported significant enhancement of the esterification activity and sulfur-leaching resistance of SO_4^{2-}/ZrO_2 by forming a homogeneous mixture of oxides (MoO_3–Nd_2O_3. MoO_3–Nd_2O_3) species mixed with ZrO_2 that stabilize the tetragonal ZrO_2 phase.

In the present work, we apply Cu/SZ catalysts using Copper as transition metal which is introduced by two different methods, and explain the effect of the introducing method on the acidity, surface area, stability of tetragonal phase and intensities of oxides and sulfates groups in the prepared catalyst and accordingly the conversion percentage of esterification reaction.

Experimental

Preparation of the catalysts

The catalysts were prepared using zirconium iso-propoxide (70%) purchased from Aldrich Chemicals, Iso-propanol (99%) and H_2SO_4 (96%), purchased from Gomhoreya chemicals and Copper acetate, purchased from Merck.

SZ600 catalyst

Preparation of the catalysts has been carried out according to a modified method [18] by 10 cm³ of zirconium iso-propoxide (70%) in 12.5 cm³ iso-propanol (99%) was mixed slowly with 0.25 cm³ H_2SO_4 (96%). The mixture was placed in a conical flask and stirred for 30 min at room temperature. The weight ratio of Zr: S was 1:0.038. A solution of 30 cm³ iso-propanol in 1.6 cm³ H_2O was added drop-wise with stirring to carry out the hydrolysis and gelation. The gel was aged for 1hr at room temperature then dried for 12 h at 120°C. The end step is calcination in static air at 600 °C for 3 hrs.

Cu/SZ/ (sol) catalyst

This catalyst was prepared by the procedure used in preparing SZ catalyst, but there was another addition during the first mixing step, that was the precursor of copper (copper acetate) (Fig.1.a).

Cu/SZ/ (imp) catalyst

The prepared SZ600 powder was impregnated in an aqueous solution containing the calculated amount of copper acetate. The paste was then dried at 110 °C overnight, then subjected to calcination in air at 400°C for 3h. (Fig.1.b)

Synthesis of Ester
Materials

Oleic acid (OA), 1-Decanol (DA) and P-Toluene Sulphonic acid monohydrate (PTSA), were purchased from Aldrich Chemicals, O-xylene was purchased from Aduic Chemicals Company.

Experimental set-up and procedure

The reaction was carried out in a four-neck glass flask equipped with a stirrer, thermometer, nitrogen gas inlet and a reflux condenser. A mixture of the free fatty acid OA (0.01 mol), alcohol DA (0.011 mol), in practice, excessive alcohol is often added since this reaction is reversible, [19], with studied catalyst (0.3-3) wt%, based on total weight of reactants, was charged in the reactor vessel under N_2 gas at 140°C for 6 h in o-xylene as a solvent. The water produced via the esterification reaction was removed throughout the course of the reaction using 'Dean and Stark separator'. At the end of the reaction, the reacting mixture was cooled to room temperature, and the catalyst was separated from the reaction mixture by centrifugation. The reaction was repeated under the same conditions by applying each prepared catalyst in different concentrations (0.3-3) wt% based on total weight of reactants.

The collected liquid product was purified and its structure was confirmed by Fourier transform infrared spectroscopy (FTIR) and Proton nuclear magnetic resonance (^{1}HNMR) spectroscopy. Gel permeation chromatography (GPC) was used to determine the average molecular weight of the prepared esters.

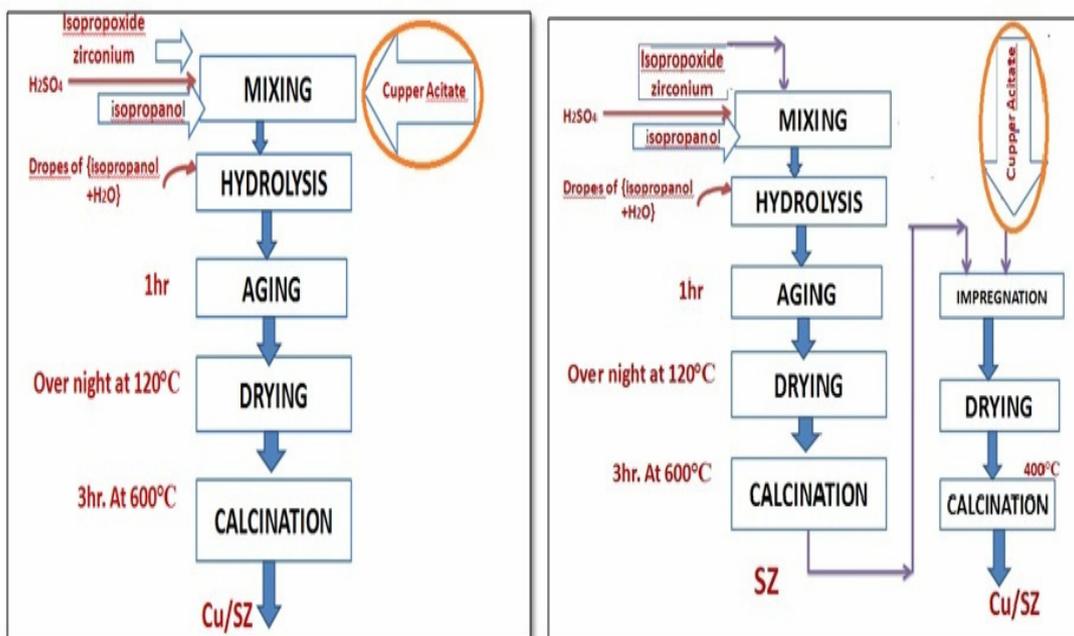

Fig. 1. Flow diagram of catalysts Preparation:

Fig.1.a Cu/SZ (sol) (Fig.1.b) Cu/SZ (imp)

The esterification reactions require bi-functional catalyst to play the two steps of protonation as the first step and deprotonation as the end step of the mechanism as shown in Fig. 2 [20]. The Cu/SZ catalysts were applied; using copper as an active agent in the deprotonation step in the mechanism of the esterification reaction.

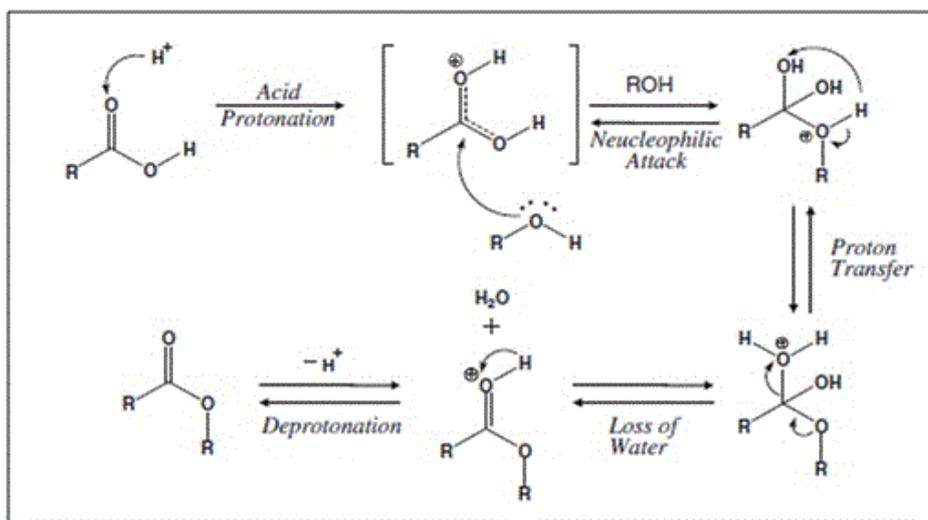

Fig . 2. Mechanism of Esterification [20].

Characterization of catalysts and products
Characterization of the Catalysts
X-ray diffraction (XRD)

All catalysts were characterized by powder X-ray diffraction (XRD) for crystallinity measurements and oxide content in the solid materials, using analytical {X0PERT PROMPD} X-ray diffractometer, Cu Ka radiation of wavelength k =1.5406 A˚, rating of 40 KV, 40 mA, step size =0.02 and scan step time of 0.4 s.

NH_3 Temperature Programmed Desorption (NH_3-TPD)

The evaluation of the acidity and its strength of the prepared catalysts were achieved by monitoring the amount of the desorbed NH_3 from the catalyst surface after exposing to stream of NH_3 for a certain period. The experiment involves adsorption of a chosen molecule at a low temperature (T_0), and then measuring its rate of desorption as the temperature is increased. The temperature (T) is normally increased at a linear rate [21].

Surface analysis

Isothermal nitrogen adsorption/desorption method was used to evaluate the specific surface area and pore size distribution of all prepared catalysts using the BET method. The BJH method was also applied for calculating the pore size and pore radius as well as the internal surface area of the prepared catalysts. These parameters were determined using Quanta chrome Nova 3200, commercial BET unit at 78 K using liquid N_2. Prior to the measurement, the samples were outgassed in a stream of 30% N_2/He mixture while being heated to 200 ^{O}C for 3 h under a reduced pressure of 10–5 Torr to remove adsorbed moisture from the catalyst surface.

Scanning electron microscopy (SEM)

Scanning electron microscopy (SEM) uses a finely focused beam of electrons in order to produce a high resolution image of a sample. SEM images have a three dimensional appearance, which is very useful while examining the surface structure of a sample. Solid catalysts' surface topography was revealed through Scanning electron microscopy SEM images Model Joel 3500 electron microscope.

Infrared spectral analysis (FTIR)

Chemical structure characterization of the solid catalysts was conducted using a Nicolet iS10 FT-IR spectrometer.

Characterization of the products
(FT-IR & 1HNMR)

All products from reactions performed in this investigation were analyzed by FT-IR in a

BIORAD-Excalibur Series FTS 3500GX system. The method of analysis varied according to the characteristics of the products. However, all of them were performed with 20 scans/min and resolution of 4 cm^{-1}.

The analyses by hydrogen nuclear magnetic resonance (¹HNMR) was recorded by a BRUKER-Advance 400 (400 MHz) spectrometer operating at 9.4 T, observing hydrogen at 400.13 MHz, in detoured chloroform solution ($CDC1_3$) using TMS as internal reference to HNMR chemical shifts.

Viscosity index measurements

Automated multi range viscometer tubes HV M472, obtained from Walter Herzog (Germany), were used to measure viscosity. Measurements were run in a Temp-Trol (Precision Scientific, Chicago, IL, USA) viscometer bath set at 40 ºC and 100 ºC. The viscosity and viscosity index were calculated using ASTM methods D 445-97 and ASTM D 2270-93, respectively.

Gel permeation chromatography (GPC)

GPC is a type of size exclusion chromatography (SEC) that separates analytes on the basis of size. The technique is often used for the analysis of polymers. GPC Extension allows flow rate and multi-detector delay corrections and includes Narrow, Broad and Broad on Narrow calibrations.

Results and Discussion

Characterization of the prepared catalysts
XRD Pattern of Cu/SZ catalysts

The XRD patterns obtained for the SZ, Cu/SZ (Imp) and Cu/SZ (Sol) catalysts are illustrated in Fig. 3.The crystal size of each phase is listed in Table 1.

Applying the Scherrerʹs equation,

$$D = K \lambda/\beta \cos \theta$$

Where: D is the average crystallite diameter, K is the shape factor, θ is the half of position angle {Bragg angle}, β is the full width of half maximum FWHM of the main peak in radians,

λ is the wave length of X-ray.

From the patterns (Fig. 3), it is clear that unloaded SZ and Cu/SZ (Imp) catalysts appear more crystalline than Cu/SZ (Sol) catalyst [22]. Figure 3a shows the XRD pattern of unloaded SZ catalyst, the peaks appearing at 2θ of 30, 35, 50 and 60° refer to tetragonal crystalline phase of $ZrO2$ [23, 24], whereas very weak peaks appear at 2θ of 28, 31 and 34° indicating the presence of monoclinic phase of $ZrO2$ in low percentage.

After Cu loading on the SZ via impregnation or sol gel techniques, tetragonal phase of ZrO2 is the phase appeared. This result demonstrates that the addition of copper contributes to stabilizing the tetragonal zirconia [25]. The intensities of all peaks are decreased after Cu loading. This lowering in intensities is more significant in case of Cu/SZ (Sol) catalyst, implying a higher dispersion of Cu ions in the matrix of ZrO2 rather than the surface of the catalyst. The same effect was observed by other researchers at high iron loadings [26]. These observations were also reported by other researchers [23-25, 27, 28]. Additional peaks are observed at 2θ of 36 and 38 corresponding to CuO monoclinic structure (JCPDS:80-0076 card ICSD≠:067850) [29-31]

In the 2θ region from 34 to 37, the peak includes tetragonal phase of zirconia and the monoclinic structure of CuO and we can observe that there is a small split in the peak of Cu/SZ (Imp) catalyst. This splitting becomes clearer in the Cu/SZ (Sol) catalyst. The broadening and lowering of the peaks of Cu/SZ (Sol) catalyst compared with Cu/SZ (Imp) catalyst indicates the formation of a composite of CuO-ZrO2.

Sulfation increases the BET area and improves the thermal stability of zirconia, preventing the reduction during high-temperature applications [32]. The TPR study for SZ prepared by sol-gel method shows that the reduction of the catalyst begins at ~700°C [23, 33, 34], so CuO- ZrO and Cu_2O can't be reduced during calcination step at 600°C. The CuO- ZrO composite is green in color (as the color of Cu/SZ (Sol)), and may be assumed to be the main contributor for the higher activity than that of the Cu/SZ (imp) catalyst.

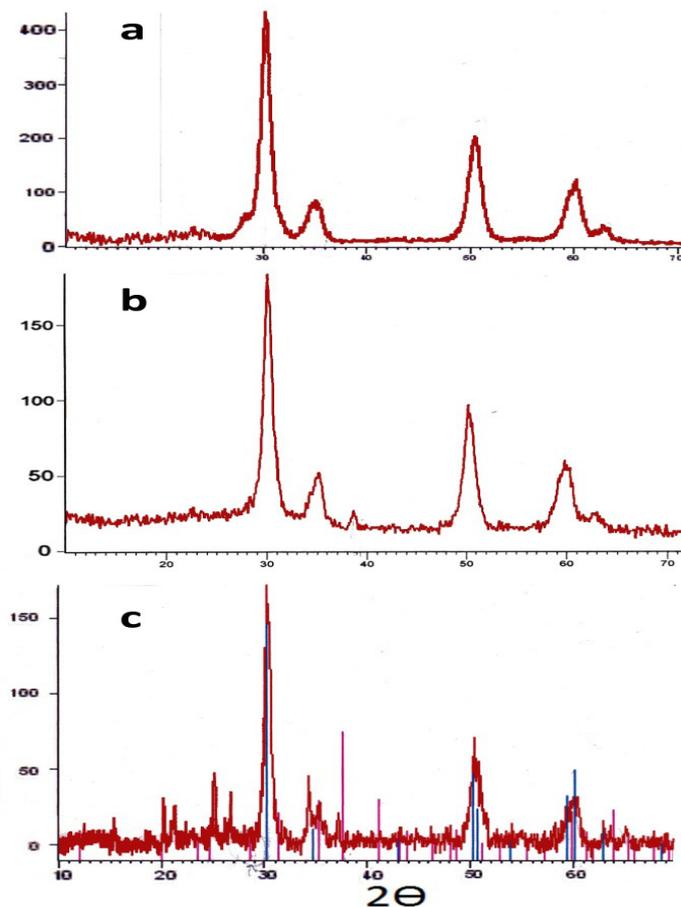

Fig. 3. XRD patterns for the prepared catalysts: (a) SZ, (b) Cu/SZ (Imp) and (c) Cu/SZ (Sol).

Temperature Programmed Desorption (TPD)

Figure 4 shows the TPD curves obtained for the unloaded and 10% Cu loaded catalysts prepared via impregnation technique (Cu/SZ (imp)) and sol-gel technique (Cu/SZ (sol)). The unloaded SZ exhibits the most pronounced ammonia desorption capacity, particularly during the high temperature region (400-500°C) which indicates that the metal loading achieved by both techniques (sol-gel and impregnation) has drastically decreased both density and strength of the acid sites in the unloaded catalyst all over the TPD range under study. The TPD peaks correspond to weak acid sites only (50-320°C) appear in the Cu/SZ (sol), but corresponds to somewhat higher

desorption temperature (50-450°C) in case of Cu/SZ (imp) catalyst. This succession of ammonia desorption temperature is well correlating with the strength of the prepared catalysts as follows: Cu/SZ (sol) < Cu/SZ (imp) `< SZ. This decrease in acidity may be due to the high copper loading in impregnation technique and due to interaction between copper metal and zirconium oxide in sol-gel technique. The amount of S content affected the physicochemical properties of the catalyst and its acidity, leading to different activity for esterification [35].

*Surface Properties of Catalysts:*

The study of the surface of the prepared

**Fig. 4. NH$_3$ temperature-programmed desorption for SZ & Cu/SZ samples.**

Fig. 5. Pore size distribution for Cu/ZS catalysts.

catalysts highlights the effect of preparation on the textural properties as shown in Table 1. Roughly speaking, the textural properties are lowest for the impregnation prepared catalyst but highest for the sol-gel prepared catalyst.

The pore size distribution calculated according to the BJH computation (Fig. 5), shows that the pore size distribution for the unloaded is like sol-gel catalysts, but different in the pore volume.

The wider pore distribution in the range of ~ 40 Å is a significant property in case of impregnation prepared catalyst. This difference can be attributed to a partial filling of the pores with copper oxide particles and accordingly to the decrease of the surface area from 111 to 18 m^2/g (Table 1). It is worth noting that Cu/SZ (sol) acquired the highest activity as a result of the large surface area (153.239 m^2/g).

TABLE 1. Textural properties of the prepared catalysts.

Catalyst	SZ	Cu/SZ(imp)	Cu/SZ (sol)
Surface area (m^2/g)	111.8	18.3	153.239
Average pore diameter (nm)	0.43	0.44	1.7
Total pore volume (Cc/g)	0.2	0.0503	0.186
Crystal size (nm)	22.6	51.8	16.9
Color	white	Black	green

Scanning Electron Microscopy (SEM) analysis

sol-gel prepared catalyst
Figure (6.a)

impregnation prepared catalyst
Figure (6.b)
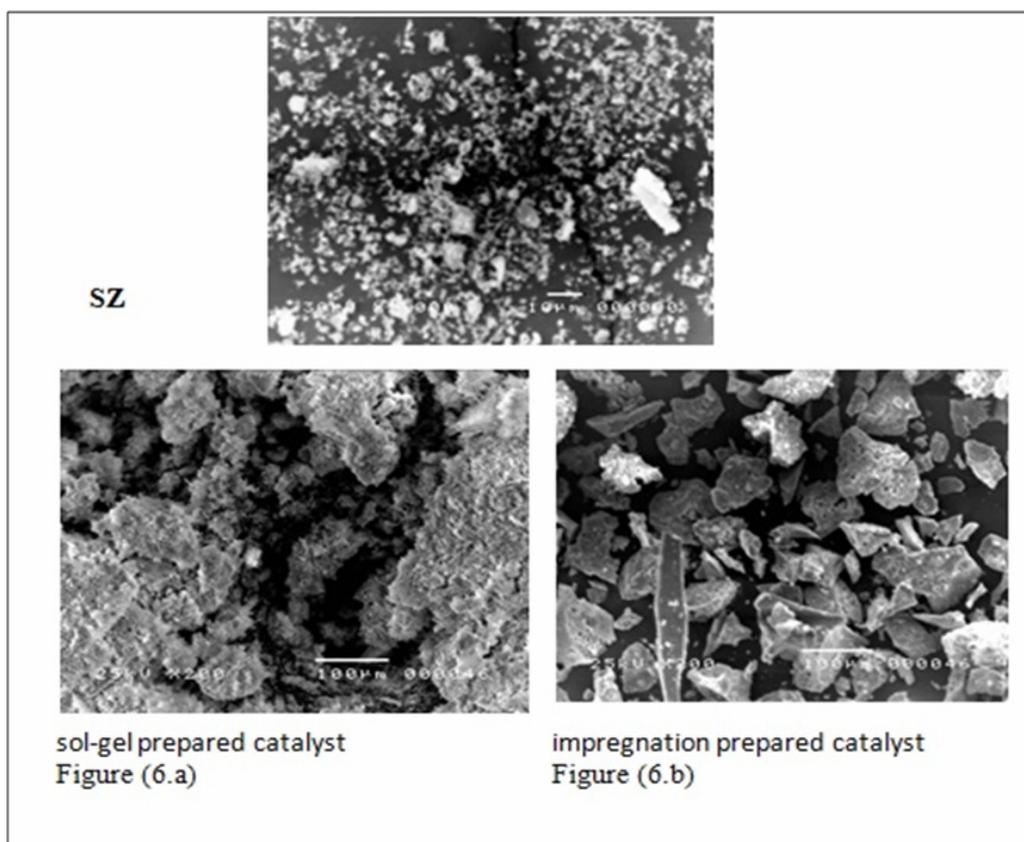

Fig. 6. Scanning Electron Microscopy (SEM) images.

Figure 6 shows the SEM images for the prepared SZ catalysts. The current catalysts exhibit different structures and colors after calcinations. The unloaded SZ has regular particle sizes and shows a high porosity white color. The impregnated Cu/SZ catalyst has also regular particles distribution, but possesses black coloration and low porosity. The third catalyst, Cu/SZ (sol), is found to be of low density and spongy in nature with high porosity in green color. The black color of the impregnated sample is referred to the presence of CuO which has a black color, mostly on the surface of the catalyst. But, the green color of the sol-gel catalyst may due to the incorporation of the Cu ions in the matrix of zirconia forming the $CuO-ZrO_2$ composite. This result is compatible with the XRD results.

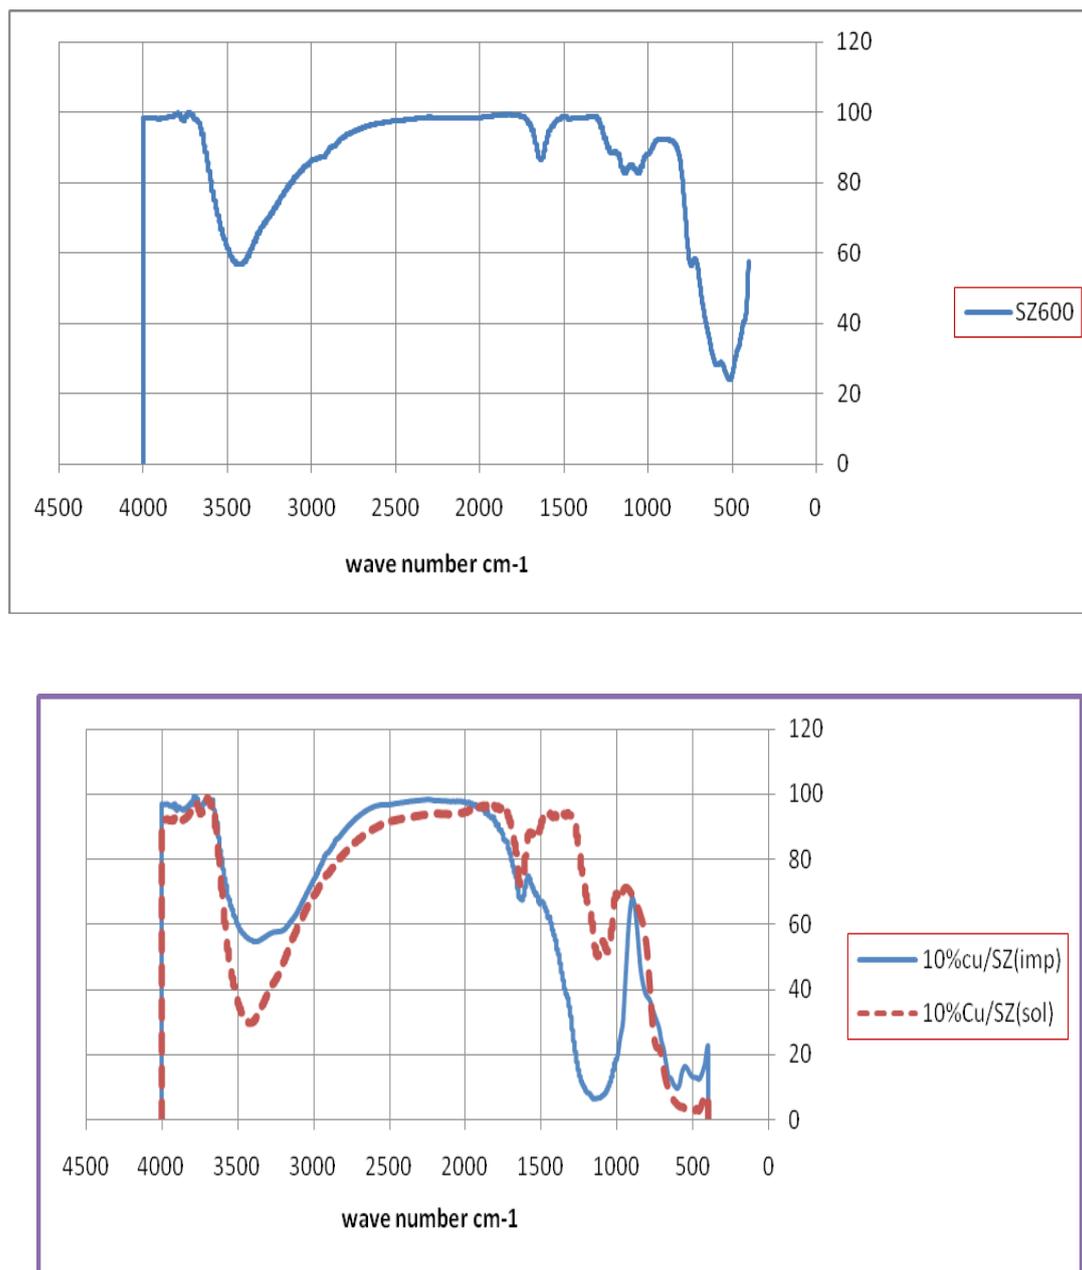

Fig. 7. IR spectra of prepared catalysts.

Infrared spectral analysis (FTIR)

The IR spectra obtained for the prepared calcined catalysts: SZ, Cu/SZ (Imp) and Cu/SZ (Sol) are shown in Fig. 7. In the hydroxyl group region, stretching vibration band appearing at 3746 and 3390 cm[-1] refer to the terminal OH group of ZrOH [23, 24, 36-38]. The broad band between 3000-3600 cm[-1] and centered at ~3400 cm[-1] is assigned to bridged Zr–OH groups.

In case of the Cu/SZ (Sol) catalyst, it is noticed that this broad band is of high intensity and shifted to a lower frequency (from 3390 to 3427 cm[-1]) relative to the corresponding peak. The reason for this shift is attributed mainly to the decrease of acid strength and the difference in preparation technique [39] intensities of these groups reflects the order of acidity of the different samples of catalyst. This is consistent with the TPD data in Fig. 4.

The sharp peak at 1630 cm[-1] is assigned to hydroxyl deformation of adsorbed water, indicating incomplete dehydration. Also this peak affected by the degree of acidity, so, it is small in case of Cu/SZ (Imp), and long in the second case. So, we can say that the OH stretching vibration band decreases by the increasing percentage loading of SO_4^{2-} This behavior may be attributed to the successive formation of H_2SO_4, HSO_4^- and SO_4^{2-} from water sensitive SO_3 groups. In Cu/SZ (sol) catalysts, the sulfate region gives sharp bands at 1128, 1054 and 977 cm[-1] which are clearly attributed to S–O bond vibrations [39-41].

Moreover, the strong broadening of these peaks is attributed to the generation of an amorphous phase coating the particles of SZ as a result of the different preparation method. Sohn and Park have prepared 1.5% $NiSO_4/ZrO_2$ catalyst, they reported that bands at 1270, 1147, 1081 and 1034 cm[-1] are attributed to the bi-dentate sulfate ion coordinated to Zr^{+4} and Ni^{+2} metals [42, 43].

The sulfate peaks for Cu/SZ (imp) catalysts were much larger than that of the Cu/SZ (sol) catalysts by integrating with TPD analysis, it is clear that tri-dentate sulfate ions coordinated to zirconia at low sulfur contents, while a 2-fold coordinated configuration was formed at high sulfur contents, i.e. the catalysts with low sulfur contents had a higher coordination configuration [33].

The absorption bands appearing at 430, 507, and 606 cm[-1] are attributed to the Cu-O stretching mode in the monoclinic phase of CuO nanostructure for Cu/SZ (imp). The highest intensity is observed for the Cu/SZ (sol) catalyst at the 1000-500 cm[-1] range due to introducing of Cu ions in the zirconia structure [44]. Peaks of zirconia at 642.3 and 449.4 cm[-1] can be observed in case of impregnation [44].

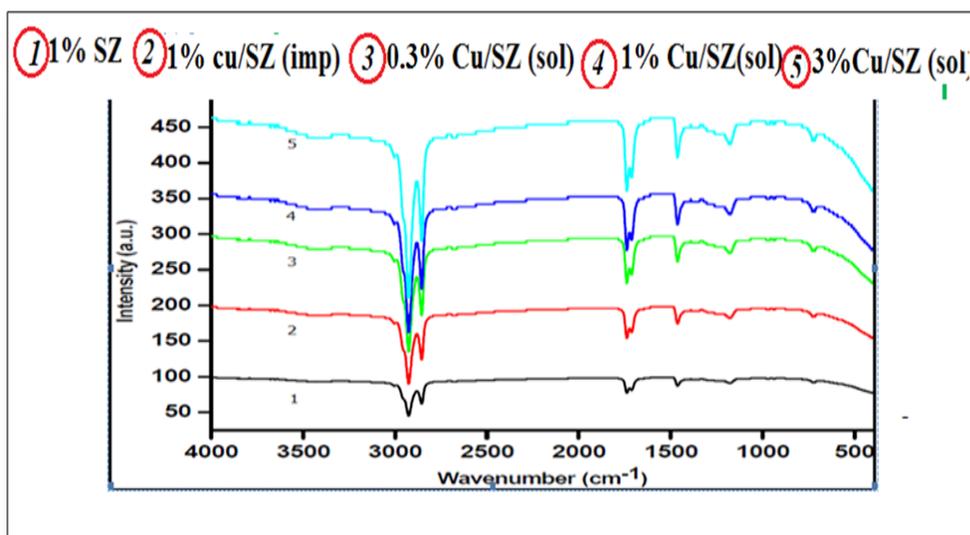

Fig. 8. FT-IR spectrum of the prepared esters.

Characterization of synthesized Ester

The chemical structures of the prepared esters were elucidated by FT-IR analysis (Fig. 8). The absorptions at 2968 and 2856 cm^{-1} were assigned to the CH$_3$ group; the absorption for CH$_2$ group in OA at 1462 cm^{-1} was obtained in all spectra of the samples. On the other hand, increasing of peak intensity at 1735 cm^{-1} which corresponds to C=O stretching of ester group, indicates the increase of conversion of carboxylic acid groups to ester groups by increasing the concentration of Cu/SZ catalyst. Furthermore, the appearance of broad peak at 1176 cm^{-1} in all spectra of the samples, which corresponds to C-O-C vibration, indicates the formation of ester in the prepared oils by using any of the prepared catalysts. The absence of the broad peak at 3450 cm^{-1} (OH stretching of COOH group) can be also attributed to formation of ester group and consumption of all hydroxyl groups during the esterification reaction.

TABLE 2. Pour point (PPT), Flash point (FP), Viscosity index (VI), Apparent Viscosity (AV), Molecular weight (Mwt) and Percentage yield values of synthetic ester oils

| Samples | | Catalyst type | Catalyst % | PPT, °C | FP, °C | Kinematic viscosity (mm2/s) | | VI | AV, Cp | Yield, % | Mwt |

Product parameters

The molecular weights of the prepared esters were determined using the GPC technique described in the experimental section. The resultant molecular weights are listed in Table 2.

The ability of a material to remain in the liquid state at low temperatures represents a quality base for number of industrial materials, such as surfactants, biolubricants, and fuels. The cold flow property of plant oils is extremely poor and limits their use at low operating temperatures, especially those used as automotive and industrial fluids. Plant oils have a tendency to form macrocrystalline structures at low temperatures through uniform stacking of the ester backbone [45]. Such macrocrystals restrict the easy flow of the system due to loss of kinetic energy of individual molecules during self-stacking. Cold flow properties of these samples were determined using their pour points. In practice, the usable liquid range is limited by the pour point (PP)

at low temperatures and the flash point at high temperatures. The PP should be low to ensure that the lubricant is pumpable when the equipment is started from extremely low temperatures. The flash point should be high to allow the safe operation and minimum volatilization at the maximum operating temperature. For the most demanding applications, such as aviation jet engine lubricants, an effective liquid range over 300 ºC may be required [46].

The oleic acid synthetic mono-esters described above were screened for low temperature behavior through determination of their pour point (PP). Therein, an improvement of the cold flow behavior of the prepared esters was realized.

The efficiency of the biolubricant in reducing friction and wear is greatly influenced by its viscosity. The viscosity must always be high enough to keep sufficient oil film between the moving parts. The Viscosity Index (VI) is an arbitrary measure for the change of viscosity with

variation in temperature. The lower the VI, the greater the viscosity of the oil changes with temperature and vice versa. The pour point (PPT), flash point (FP), viscosity index (VI), apparent viscosity (AV) and percentage yield values of synthetic ester oils were evaluated and recorded in Table 2.

An important property of lubricants is their ability to maintain a stable lubricating film at the metal contact zone. Chain length of the fatty acid of plant oils is known to provide excellent lubricity due to their ester functionality where, the polarity of the ester molecule attached to metal surface allows a monolayer film formation with the non-polar end of fatty acid chains sticking away from the metal surface. The ester structures offer active oxygen sites that trigger binding on the metal surface forming a protective film which builds further with time to reduce friction [47, 48].

Conclusion

The difference in preparation techniques revealed significant effects on all prepared catalysts 'characterization. The preparation by sol-gel technique produces a stable, high surface area catalyst with low-to medium acidity which is suitable to apply in esterification reaction that needs this degree of acidity and high surface area. This method eliminates formation of surface sulfates which can, in the presence of water produced from esterification reaction, causes many problems. So, it is more suitable to apply sol-gel technique in the preparation, to achieve high yield and quality of lubricating oil.

تحضير حفاز من الزركونيا المكبرتة المدعم بفلز النحاس بمقياس النانو و تطبيقه الصديق للبيئة في تصنيع مواد التشحيم الحيوية

امينة حمدي ابراهيم، حسين شافعي اسماعيل ابراهيم، دعاء سمير الدسوقي، سميرة عبد العظيم، نهى أحمد قدرى أبو الغيط

معهد بحوث البترول المصرى ـ القاهرة ـمصر.

تمت دراسة تأثيراستخدام حفاز الزركونيــا المكبرتة المدعم بفلـز النحاس على عملية استــرة الأحماض الدهنية ، وقد تم تحضير ثلاثة حفازات (Cu/SZ/ (imp) and (Cu/SZ/ (sol) ,SZ) اخر أثنين يحتويان على ١٠٪ من النحاس المدعم على الزركونيا المكبرتة (Cu/SZ) بطريقة التشريب الرطب (Cu/SZ/ (imp) و بطريقة السول-جيل (Cu/SZ/ (sol)). تم توصيف الحفازات التي تم تحضيرها بواسطة حيود الأشعة السينية (XRD)، و درجة الحرارة المبرمجة لامتزاز الأمونيا (TPD)، وامتزاز النيتروجين، و مطياف فورييه للأشعة تحت الحمراء (FTIR)، وتصويرها بواسطة المجهر الإلكتروني (SEM)، تحميل النحاس على الحفاز الحالي (SZ) أدى إلى تغيرات كبيرة في التركيب والنسيج. وأدى تحميل فلز النحاس الى تثبيت التركيب الرباعي للزركونيا Tetragona الاكثر فاعلية, و أيضا تكوين متراكب من (CuO-ZrO). وأظهرت دراسة دراجات امتزازالامونيا على سطح الحفاز عند درجات حرارة مبرمجة (TPD) أن تداخل أيونات ال Cu في بنية الزركونيا (Zirconia lattice) بطريقة سول-جل قد تسبب في خفض الحامضية أكثر مما يفعل طريقة التشريب الرطب .كتطبيق صديق للبيئة, استخدمت الحفازات المحضرة بتركيزات مختلفة عند نفس ظروف التفاعل فى تحضير زيت تشحييم حيوى عن طريق تفاعل استرة الأحماض الدهنية واظهرت هذه الدراسة أن(Cu/SZ/) (sol) الحفاز ذو الحامضية المنخفضة هو الاكثر فاعلية حتى عند اقل التركيزات المستخدمه , أثبت أنه يمتلك أعلى نشاط، وبلغت نسبة إنتاجية مواد التشحيم الحيوية ٩٩,٨٪ عند استخدام نسبة ٠,٣ من الحفاز المحدد المستخدم. كما تم تعيين نقطة الأنسكاب، نقطة الوميض، مؤشر اللزوجة، اللزوجة الظاهرية و كذلك تعيين قيم النسبة المئوية للناتج من زيوت الأستر المحضرة.
